INTRODUCTION

Chronic pain is one of the most common health issues posing a significant economic strain on society. Amid the current opioid crisis, there is a need to explore alternative but effective non-drug pain therapies. Causalgia, known as complex regional pain syndrome type II (CRPS II) arises after an injury or trauma to a peripheral nerve.¹ Dorsal Root Ganglion Stimulation (DRG-S) is more effective than spinal cord stimulation in treating CRPS of lower extremities due, in part, to its targeted coverage to challenging focal pain areas.² The goal of the sub-analysis of data from the prospective, multi-center, REALITY study (NCT03876054) is to assess the effectiveness of DRG-S in treating Causalgia of the lower extremities - knee and ankle/foot pain patients.

METHODS

Subjects enrolled in the REALITY study (NCT03876054) who received DRG-S treatment for knee (KS) or ankle/foot (AFS) were identified. Baseline and 6m follow-up data were collected for change in pain intensity (0-10 numeric rating scale-NRS), physical function, fatigue, and pain interference (PROMIS-29 questionnaire). Data was compared within groups (Knee vs. Ankle/foot).

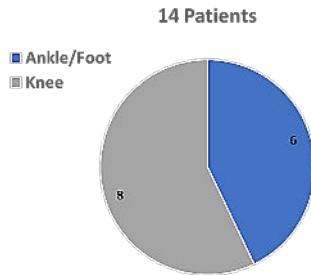

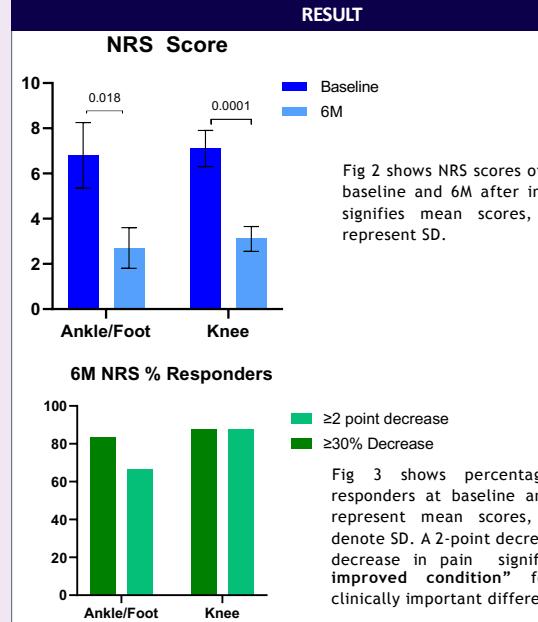

Fig 1 shows the ratio of Ankle/Foot subjects (AFS) vs. Knee pain subjects (KS) who received DRG-S.

Mean (SD) baseline pain intensity decreased from 6.8 (± 2.9) to 2.7 (± 1.6) in AFS and 7.1 (± 1.8) to 3.1 (± 1.1) in KS. >66.7% of AFS and 75% of KS reported a 50% decrease in pain signifying “substantial improvement” for minimal clinically important differences. >66.7% reported ≥ 2 -point decrease in pain scores indicating “much-improved condition” for minimal clinically important differences for both cohorts.

Physical function improved with a 67% increase in both groups as well as a decrease in fatigue and pain interference. 75% of subjects were satisfied with DRG-S for KP and 66.7% for AFP.

RESULT

DISCUSSION

DRG-S is effective in reducing Ankle/Foot pain and Knee pain from CRPS II. More than 71.4% (10/14) subjects reported 50% decrease in pain.

PROMIS-29 scores indicate patients observed improved psychosocial effects such as less anxiety, decrease in depression and fatigue alongside improved physical function and sleep.

CONCLUSION

In summary, at 6 months, DRG-S subjects reported improvements in pain and physical function. Our preliminary results indicated DRG-S is an effective therapy for patients with lower extremities causalgia knee or ankle/foot.
